- [I wrote a trigger to create an application with custom metrics. Can I view the custom metrics in the application?](#)
- [To see metrics in one place, can I build a dashboard instead of an application?](#)
- [I created an application through the Web UI. What if I want to collect more complex metrics for that application?](#)

What is the All Activity application?

The All Activity application is a built-in application that aggregates metrics for all devices on your network.

Why is there unexpected metric activity in my application?

Unexpected activity might be a result of one or more triggers written to send traffic to the application. For example, if you see metrics from devices or protocols that are not selected in the Web UI configuration of the application, it might be from the devices the trigger is assigned to or the events the trigger runs on.

Why can't I delete an application?

To preserve historical data, applications cannot be deleted. If, over time, an application stops seeing metric activity, it becomes inactive. For example, if you remove data sources from an application, disable any triggers associated, or if the assigned sources themselves are inactive, the application becomes inactive.

From the Applications page, you can sort the applications list to view only active applications.

The screenshot shows the 'Sources' sidebar on the left with 'Applications' selected. The main content area has a search bar with 'Any Column' and '=' dropdowns. To the right of the search bar is a 'Show' button with two options: 'All' and 'Active'. The 'Active' button is circled in red. Below the search bar is a table with columns 'Name' and 'Description'.

<input type="checkbox"/>	↑ Name	Description
<input type="checkbox"/>	All Activity	Default application container for all activity
<input type="checkbox"/>	Loc234 Databases	Monitor DB traffic, location234
<input type="checkbox"/>	Active Directory R47	Monitor traffic over AD devices in Group R47

Why can't I change the application ID?

The application ID is referenced by triggers that send traffic to the application. Modifying the application ID might break a trigger or result in the trigger creating a duplicate of the original application.

What are the REST API application properties for?

The REST API properties are unique identifiers that you reference to perform configuration tasks through the ExtraHop REST API. For example, to retrieve details for a specific application through the REST API, you must enter the API ID for the application.

From the Overview page of an application, click **Properties** to view the REST API details.

[← Back to Applications](#)

Active Directory R47	Name	Active Directory R47	Description	Monitor traffic over AD devices in Group R47	Type	API ID Trigger ID	Application	6 activeDirect...	Manage Application Properties Alerts
-----------------------------	------	----------------------	-------------	--	------	----------------------	-------------	----------------------	---

When should I write a trigger to create an application?

Write a trigger if you need an advanced application, such as in the following examples:

- You want advanced filtering, such as collecting traffic only when HTTP 404 responses occur.
- You want to commit custom metrics to the application.
- You want to collect metrics from non-L7 traffic such as Flow or TCP.

I wrote a trigger to create an application with custom metrics. Can I view the custom metrics in the application?

Custom metrics cannot be viewed from an application; applications only display built-in metrics. Although the custom metrics are committed to the application, you must [create a chart](#) to view custom metric data.

To see metrics in one place, can I build a dashboard from multiple devices instead of an application?

Yes, dashboards are another method for viewing the metrics you want in one place; however, a dashboard requires you to manually build and maintain charts for the metrics you want, which takes time and consumes more resources.

I created an application through the Web UI. What if I want to collect more complex metrics for that application?

You can commit additional metrics to an existing application by adding a trigger that references the Application ID (also known as the Trigger ID). To find the Application ID, log into the ExtraHop Web UI and navigate to your application. Then, click on the **Properties** link from the top-right of the Overview page. The Application ID is displayed near the bottom left of the Properties window.

Next, write your trigger and include the Application ID as `Application('<app_id>')`. For example, the following lines commit a metric to track HTTP 404 errors for an application that has an Application ID of HQservers :

```
if (HTTP.statusCode === 404){
    Application('HQservers').metricAddCount("HTTP 404s", 1);
}
```

For more information about committing metrics to applications, see [Create an application through the Trigger API](#).
